

Lead Exposure In Children Affects Brain And Behavior

No. 45; Updated October 2017

Lead exposure is one of the most common preventable poisonings of childhood. Data from the Center for Disease Control (CDC) show that 6% of all children ages 1-2 years and 11% of black (non-Hispanic) children ages 1-5 years have blood lead levels in the toxic range. Lead is a potent poison that can affect individuals at any age. Children with developing bodies are especially vulnerable because their rapidly developing nervous systems are particularly sensitive to the effects of lead.

Almost all children in the United States are exposed to some lead. Common sources include lead paint and lead contained in water and soil. Housing built before 1950 has the greatest risks of containing lead-based paint. Some children may also eat or swallow chips of paint (eating unusual/nonnutritious things is called pica) which increases their risk of exposure to lead.

Exposure to lead can have a wide range of effects on a child's development and behavior. Even when exposed to small amounts of lead levels, children may appear inattentive, hyperactive, and irritable. Children with greater lead levels may also have problems with learning and reading, delayed growth, and hearing loss. At high levels, lead can cause permanent brain damage and even death.

Early identification and treatment of lead poisoning reduces the risk that children will suffer permanent damage. Treatment begins with removal of the child from the sources of the lead. Medications can remove lead from the body.

Early identification and treatment of lead poisoning reduces the risk that children will suffer permanent damage. Treatment begins with removal of the child from the sources of the lead. Medications can remove lead from the body.

For additional information about lead poisoning, contact your physician, county, or state Department of Health. You can also contact:
